Points to Ponder Before Selecting a Portable Oxygen Concentrator (POC)
Sam P. Giordano, MBA, RRT, FAARC, Consultant for AARC

Over the past several years, there have been some tremendous breakthroughs in the area of long-term oxygen therapy support. One of the most notable is that of the oxygen concentrator.

Unlike gaseous or liquid oxygen that are the products of oxygen manufacturing companies, oxygen concentrators actually ‘make’ their own oxygen by removing nitrogen from atmospheric air. Recalling our high school science class when we were taught that atmospheric air is composed of approximately 79% nitrogen and 21% oxygen, oxygen concentrators concentrate the oxygen from atmospheric air by filtering out or separating the nitrogen from the oxygen. The oxygen passes through the filter system and is then stored within the device (storage volumes vary from device to device) and is available for breathing by the patient.

Twenty years ago, there were no portable oxygen concentrators (POCs). There were only stationary oxygen concentrators that were relatively large and quite heavy. But in most instances, these stationary units were capable of producing continuous flows of oxygen at flows up to 5 liters per minute.

However, in the last decade we witnessed the advent of the portable oxygen concentrator. Portable concentrators are lighter in weight - some weigh as little as 5 pounds! In addition to standard household AC 110 current, POCs can also be powered from the DC outlet found in motor vehicles, and from rechargeable batteries. Portable concentrators have open entirely new vistas by making it possible for oxygen patients to take their oxygen with them whenever, wherever and however they decide to do so.

POCs can be classified as able to deliver continuous flow (CF) or intermittent flow (IF). So a choice has emerged for oxygen users: Should I select a continuous flow or intermittent flow device? Please bear this in mind as you review the following information. As you will see on Table 1, some POCs are capable of delivering both continuous and intermittent flows while others are capable of intermittent flow only. Please note that intermittent flow devices, unlike machines with continuous flow capabilities, only deliver oxygen during inhalation – oxygen is NOT delivered during exhalation. By and large, this oxygen delivery method can meet the supplemental oxygen needs of most patients.

You may find that the oxygen delivery pattern of some POC devices will provide you with the supplemental oxygen necessary to increase the amount of oxygen in your blood required at both minimum and maximum activity levels. How do you know what’s best for you? The best way to learn the answer is to use a particular model POC and then use an accurate pulse oximeter to continuously record the percentage of oxygen saturation in your blood during normal activities. Supplemental oxygen should be prescribed with the goal of maintaining an oxygen saturation range identified by your physician as the maximum and minimum range for you, both at rest and during activities.

POCs can be extraordinarily liberating for many, but only if the POC selected first meets your physiologic needs. In other words, no matter what device is chosen, it must first and foremost achieve goal number
one for you and that is to relieve your hypoxia while you carry out normal activities of daily living during the entire time it is being used.

**Tradeoffs**

As with all things in life, the decision to select the right POC is sprinkled with tradeoffs. Virtually all patients want a POC that meets their needs for oxygenation at all activity levels. They also want this device to be small, lightweight, easy to carry, have an extended battery life sufficient to allow users to travel freely, and to be relatively inexpensive.

Each and every one of the foregoing is important, but in order for consumers to make the right choice in conjunction with their physicians and therapists, it is helpful to undertake a simple prioritization exercise. Since we already know that the number one priority of all supplemental oxygen delivery devices is to relieve low blood oxygen levels, it is highly recommended that when considering a portable oxygen concentrator that you first ‘test-drive’ the device while using an accurate pulse oximeter. You first, and foremost, must establish that the device can meet your supplemental oxygenation needs during your various activities of daily living (i.e., sitting, walking, and climbing stairs).

Suffice it to say, that if a particular POC model/device is tried and is unable to adequately oxygenate you, that POC model/device is not appropriate for you. That does not mean that the device wouldn’t work for others, but it does mean that this particular device is not a good clinical fit for you. All the devices on the market have a place but not all devices on the market can meet all oxygen user needs. We first must have a good fit from a physiologic standpoint. We now have narrowed the list down after applying this first criterion, and we now have a more limited list. Now is the time to use the results of our prioritization exercise. What’s the next important criterion considering your needs? Is it weight? Is it battery life? Is it price? Only you can decide this with assistance from your attending physicians and respiratory therapists.

As a general rule of thumb, the more robust portable concentrators (i.e., those that are able to supply patients with the highest oxygen needs) tend to be the heaviest. And, not surprisingly, they tend to have a shorter battery life than the more lightweight but less robust systems. When you think about it, it stands to reason that the hardware and software required to ‘make’ larger volumes of oxygen from atmospheric air require higher power requirements. Moreover, their larger physical size is a huge influence on the weight of the device. That’s why some have carts and wheels.

As you review the following Tables, you will see the performance characteristics as reported by the companies that manufacturer this equipment. This survey was done so that you could get information in an organized fashion comparing one device to the next and then make an informed decision on what POC will work best for you.

You should also keep in mind that your oxygen requirements may change over time, which should be taken into consideration when deciding whether to rent or purchase a unit. That is, if you are at the maximum settings now, this unit may not meet your needs in the future.
Some users have mentioned that they would like to see alarms on some devices. This is especially important in devices that are used by patients who might develop low oxygen levels while sleeping. Such additional feature reviews are beyond the scope of this first survey. However, we ask that after you review information in the accompanying report that you send us questions describing what else you feel you need to know in order to:

A. Have your supplemental oxygenation needs met while using a POC,

B. Make sure your doctor and home care company have adequate technical information on POC performance so your needs can be matched with the best device, and

C. Help you maximize use of the device as prescribed by your doctor so that you achieve the best possible benefits.

Other Considerations

As a rule of thumb, all supplemental oxygen devices that are capable of continuous flow are designed and calibrated to deliver flow in liters per minute. This traditional designation has been used for well over 70 years. In the hospital you may recall seeing oxygen flow meters plugged into the wall outlets located at the head of the bed. These flow meter devices deliver continuous flow and are calibrated in liters per minute.

Devices that provide intermittent flow cannot use the designation *liters per minute* since there is no continuous flow. As an alternative, you will note that some devices are calibrated in *milliliters per breath*, known as a *fixed bolus volume* while others are calibrated in *milliliters per minute*, known as a *fixed minute volume*. The difference in these units is traceable to how the device actually ‘makes’ oxygen (or removes nitrogen). Which is better? Once again, it depends on the user. As you will see in the Tables, many of the intermittent flow only devices produce a predetermined, fixed amount of oxygen per minute and per setting, commonly referred to as a *fixed minute volume* method and other devices use a *fixed bolus volume* method (bolus is defined as the amount of oxygen in milliliters delivered per breath). These may sound similar but there are some specific differences in these two methods that you should be aware of, although both methods are shown to be clinically effective.

- **Fixed Bolus Volume.** This method of oxygen delivery uses a predetermined bolus size that is calculated for each POC setting. Regardless of breathing rate, the POC delivers the same bolus volume per breath for the given setting. For example, if a POC on setting 2 delivers 15 milliliters per breath, it would deliver that same 15 milliliter bolus per breath if the breathing rate was 20, 30 or 35. At very high breathing rates, some fixed bolus POCs may experience a drop in the oxygen purity because the total volume of oxygen being delivered in the course of each minute exceeds the production capacity for the specific setting.

- **Fixed Minute Volume.** This method of oxygen delivery establishes a predetermined volume of oxygen that will be produced for each POC setting over the course of a minute. The bolus amount delivered per breath is mathematically determined by the breathing rate (minute
volume ÷ breathing rate). Since the amount of oxygen produced per minute remains steady as the breathing rate increases, the amount of oxygen delivered per breath becomes smaller. Conversely, as your breathing rate decreases, the bolus size gets larger. For example, a POC with a fixed minute volume of 300 milliliters of oxygen at the 2 setting would deliver 30 milliliters per breath at a breathing rate of 10, 15 milliliters per breath at a breathing rate of 20, and so on. In all cases, the total amount of oxygen delivered each minute remains steady, as should the oxygen purity.

Please keep these performance differences in mind when selecting a POC. It bears repeating that the only way to know for sure that a supplemental oxygen user’s oxygenation levels are within the targeted range prescribed by the physician is to use a pulse oximeter to directly measure the oxygen saturation at minimum and maximum required levels. Then and only then, will you be assured that the POC, or POCs, you have selected will meet your physiological needs and embrace the priorities concerning weight, battery life, etc. that you have identified beyond those needs.

Acknowledgments

I want to acknowledge the support and collaboration of the following individuals that assisted in organizing and implementing this survey. I’m proud to say that 100% of the manufacturers that we asked to participate did so. If you have questions that are specific to their devices, please feel free to contact them directly. They are AirSep, Caire Sequal, DeVilbiss Health Care, Inogen, Inova Labs, Invacare, Philips Respironics, Precision Medical, O2 Concepts, Oxus, Inc. Thank you one and all for helping us help our patients understand the value of your products.

I also want to acknowledge individuals who have assisted with the survey and presentation of its results. First, I want to thank Greg Spratt, BS, RRT, CPFT, AARC’s current Chair of the Home Care Section. Greg is currently the Director of Clinical Marketing at Covidien. I also want to thank Joe Lewarski, BS, RRT, FAARC, a Past Chair of AARC’s Home Care Section for his assistance and guidance. Joe is currently the Vice President of Clinical Affairs at Invacare Corporation.

Bob McCoy, RRT, FAARC, and Ryan Diesem were also asked to contribute. Bob is a Past Chair of AARC’s Home Care Section and Ryan, who is Bob’s partner, has permitted me to call on him in order to draw on his extensive experience in this area of our technology. Bob is currently the Managing Director for Valley Inspired Products. Finally, I want to thank Patrick Dunne, MEd, RRT, FAARC, yet another Past Chair of AARC’s Home Care Section, but also a Past President of AARC, who works as an independent consultant with extensive experience in respiratory home care and supplemental oxygenation. Without the advice and support from the foregoing group, our ability to present this information would be much diminished.

Summary

Technology can be a boon or it can be a curse. It’s up to us to master emerging technologies, especially within the realm of respiratory care. Even though POC technology is still in its infancy, we are already seeing significant performance improvements in the category. I suspect that POC technology is about
where laptop computers were five to ten years ago. If so, we are on the verge of a technological explosion in the area of supplemental oxygen that will provide not only more effective devices to meet patients’ needs, but also package these devices in lightweight systems that will stretch battery life beyond current levels. Portable oxygen concentrator technology will not only liberate, but it will also enable patients with chronic lung diseases to enjoy a higher quality of life by staying more active. Many of us feel that increased activity levels, with supplemental oxygen when needed, will go a long way towards minimizing expensive chronic pulmonary disease exacerbations.

In closing, I want to invite all of you to submit questions that you may have to my attention at AARCPOC@aarc.org. The AARC sees this as a first in what will be a series of surveys to help our community which consists of, first and foremost, our patients, followed by respiratory therapists, physicians, nurses. All need to understand how POCs work and how to make sure every POC ordered by any physician for any patient and provided by any home care company is the proper match for the patient under all conditions of use.

Thank you.

- breaths per minute
- Oxygen purity at lowest setting: 90% -3/+5.5
- Oxygen purity at highest setting: 90% -3/+5.5

**Manufacturer Notes**

*Bolus size (in mls) is variable and changes with the patient’s breathing rate to provide a fixed minute volume of oxygen

* Focus, FreeStyle, and FreeStyle 5 units manufacturer and deliver a constant per minute volume of oxygen for each setting. As a patient’s breath rate changes, the amount of oxygen that they are receiving per bolus varies, yet the total amount received per minute remains constant.

*Oxygen concentration is the same for all breathing rates because the unit produces a set per minute volume

### Manufacturer Notes

*Fixed Minute Volume Technology*

*Invacare uses fixed minute volume technology in their pulse dose devices. Each setting will deliver a fixed amount of oxygen over the course of a minute; individual bolus amounts will be determined by the breath rate of the patient over the course of that minute.*

Oxygen purity at lowest setting: 95%

Oxygen purity at highest setting: 95%

**Manufacturer Notes**

*The EasyPulse POC setting volume specifications, as stated in their literature, are in minute volume. To determine bolus size at a specific breath rate, you divide minute volume by the breath rate.*
The survey is being sent to the manufacturers of portable devices used to deliver long-term oxygen therapy via continuous flow (CF), intermittent/pulse flow (IF), or both modes. Such equipment would include the following:

- **Portable oxygen concentrators (POCs) delivering IF only, or**
- **Portable oxygen concentrators (POCs) capable of delivering both CF and IF**

Some will receive more than one survey instrument since we have you listed as manufacturing more than one such device, and one survey per specific model is requested. If you need additional survey instruments, we will be happy to accommodate your request.
